# group theory - week 6

# For fundamentalists

## Georgia Tech PHYS-7143

**Homework HW6**                                due Tuesday, October 3, 2017

---

== show all your work for maximum credit,

== put labels, title, legends on any graphs

== acknowledge study group member, if collective effort

== if you are LaTeXing, here is the  source code

---

Exercise 6.1 *3-disk symbolic dynamics*                                2 points

Exercise 6.2 *Reduction of 3-disk symbolic dynamics to binary*        3 points

Exercise 6.3 *3-disk fundamental domain cycles*                        2 points

Exercise 6.4 *$C_2$-equivariance of Lorenz system*                    3 points

**Bonus points**

Exercise 6.5 *Proto-Lorenz system*                                  10 points

Total of 10 points = 100 % score. Extra points accumulate, can help you later if you miss a few problems.

### 2017-09-26 **Predrag** Lecture 11 Symmetries and dynamics

So far we have covered what any QM fixated Group Theory textbook since 1930's and on covers. Today to turn to what we actually use group theory for *today*, *here*, in Howey, and there is no book but ChaosBook.org.

Many fundamental problems of fluid dynamics and more generally non-linear field theories are studied in experimental settings equipped with symmetries. That is the subject of *dynamical systems theory* (of which classical, quantum and stochastic mechanics and field theories are but specialised branches). We start gently, with perhaps the simplest physical example, the three disk game of pinball.

Read ChaosBook.org Chapter 10 *Flips, slides and turns* (last updated Sept 27, 2017). There is also ChaosBook.org Appendix 10 *Discrete symmetries of dynamics* that you probably do not need. You already know much of the material covered in the text, so best to go straight to example 10.7 *Subgroups, cosets of $D_3$*, example 11.6 *3-disk game of pinball - symmetry-related orbits*, example 11.7 *3-disk game of pinball - cycle symmetries*, example 11.10 *3-disk game of pinball in the fundamental domain*, and then work your way backward, if there is something you do not understand off the bat..

### 2017-09-28 **Predrag** Lecture 12 Fundamental domain

Lorenz flow example. Read ChaosBook.org Chapter 11 *World in a mirror* (last updated Sept 27, 2017). Maybe start with example 10.6 *Equivariance of the Lorenz flow*, example 11.8 *Desymmetrization of Lorenz flow*, and then work your way back if needed.

The reading and the homework for this week, is augmented by - if you find that helpful - by 'live' online blackboard lectures: click here.

## 6.1   Discussion

Some discussion of eigenfunctions over fundamental domains - maybe of interest to Kevin, but feel free to ignore...

**2017-10-05 Predrag** Heilman and Strichartz [1] *Homotopies of Eigenfunctions and the Spectrum of the Laplacian on the Sierpinski Carpet*, arXiv:0908.2942, is not an obvious read for us, but they compute a spectrum on a square domain, and we might have to be mindful of it: " Since all of our domains are invariant under the $D_4$ symmetry group, we can simplify the eigenfunction computations by reducing to a fundamental domain. On this domain we impose appropriate boundary conditions according to the rep-resentation type. For the 1-dimensional representation, we restrict to the sector $0 \leq \theta \leq \pi/4$. Recall that the functions will extend evenly when reflected about $\theta = 0$ in the 1++ and 1– cases, and oddly in the 1-+ and 1+- cases. Note that performing an even extension across a ray is equivalent to imposing Neumann boundary conditions on that ray. Similarly, the odd extension is equivalent to Dirichlet conditions. For the 2-dimensional

representation our fundamental domain is the sector $0 \leq \theta \leq \pi/2$, and we impose Neumann boundary conditions on the ray $\theta = 0$ and Dirichlet conditions on the ray $\theta = \pi/2$. Note that our fundamental domains are simply connected. "

This seems to be saying that one gets the 2-dimensional representation by doubling the fundamental domain and mixing boundary conditions. Do you understand that?

**2016-02-21 Boris** Here is my present understanding of the fundamental domains issue: If you want simple boundary conditions like Dirichlet or Neumann you stick to 1d representations only. They connect eigenfunction to itself at the fundamental domain boundaries – otherwise you would need to connect pair of functions (would be something like boundary conditions for spinor in case of 2d representations.) So what you do is the following: take the largest abelian subgroup $Z_2 \times Z_2$ (for D$_4$ ) and split its spectrum with respect to its fundamental domain defined as 1/4 of the square (twice the fundamental domain of the full group). Then your see that Dirichlet-Dirichlet and Neumann-Neumann Hamiltonians still have $Z_2$ symmetry so your split them further into the Hamiltonians of the 1/8 fundamental domain. But Dirichlet-Neumann remains 1/4th of the square.

**2016-02-22 Predrag** Your argument is in the spirit of Harter's class operators construction of higher-dimensional representations by using particular chains of subgroups, but I am not able to visualize how that larger fundamental domain (of the lower-order subgroup) folds back into the small fundamental domain of the whole group. How I think of the fundamental domain is explained in my online lectures, Week 14, in particular the snippet Regular representation of permuting tiles. Unfortunately - if I had more time, that would have been shorter, this goes on and on, Week 15, lecture *29. Discrete symmetry factorization*, and by the time the dust settles, I have the symmetry factorization of the determinants that we need, but I do not have a gut feeling for the boundary conditions that you do, when it comes to higher-dimensional irreps.

Copied here are a few snippets from this week's lecture notes, needed here just because exercises refer to them - read the full lecture notes instead.

**Definition: Flow invariant subspace.** A typical point in fixed-point subspace $\mathcal{M}_H$ moves with time, but, due to equivariance

$$f(gx) = gf(x)\,, \tag{6.1}$$

its trajectory $x(t) = f^t(x)$ remains within $f(\mathcal{M}_H) \subseteq \mathcal{M}_H$ for all times,

$$hf^t(x) = f^t(hx) = f^t(x)\,, \quad h \in H\,, \tag{6.2}$$

i.e., it belongs to a *flow invariant subspace*. This suggests a systematic approach to seeking compact invariant solutions. The larger the symmetry subgroup, the smaller $\mathcal{M}_H$, easing the numerical searches, so start with the largest subgroups $H$ first.

We can often decompose the state space into smaller subspaces, with group acting within each 'chunk' separately:
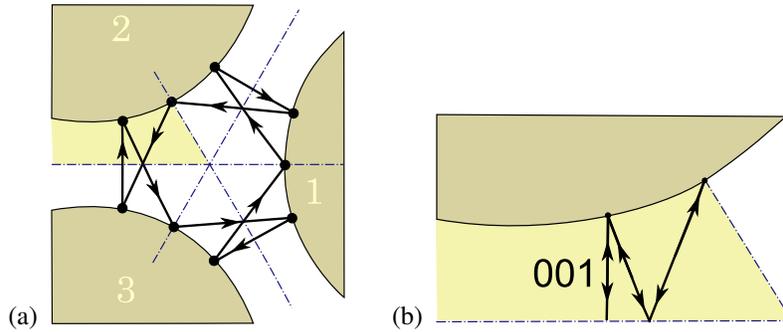

Figure 6.1: (a) The pair of full-space 9-cycles, the counter-clockwise $\overline{121232313}$ and the clockwise $\overline{131323212}$ correspond to (b) one fundamental domain 3-cycle $\overline{001}$.

**Definition: Invariant subspace.** $\mathcal{M}_\alpha \subset \mathcal{M}$ is an *invariant* subspace if

$$\{\mathcal{M}_\alpha \mid gx \in \mathcal{M}_\alpha \text{ for all } g \in G \text{ and } x \in \mathcal{M}_\alpha\}. \tag{6.3}$$

$\{0\}$ and $\mathcal{M}$ are always invariant subspaces. So is any $\text{Fix}(H)$ which is point-wise invariant under action of $G$.

**Definition: Irreducible subspace.** A space $\mathcal{M}_\alpha$ whose only invariant subspaces under the action of $G$ are $\{0\}$ and $\mathcal{M}_\alpha$ is called *irreducible*.

**Example 6.1.** *Equivariance of the Lorenz flow.* *The velocity field in Lorenz equations [2]*

$$
\begin{bmatrix} \dot{x} \\ \dot{y} \\ \dot{z} \end{bmatrix} = \begin{bmatrix} \sigma(y-x) \\ \rho x - y - xz \\ xy - bz \end{bmatrix} = \begin{pmatrix} -\sigma & \sigma & 0 \\ \rho & -1 & 0 \\ 0 & 0 & -b \end{pmatrix} \begin{bmatrix} x \\ y \\ z \end{bmatrix} + \begin{bmatrix} 0 \\ -xz \\ xy \end{bmatrix} \tag{6.4}
$$

*is equivariant under the action of cyclic group $C_2 = \{e, C^{1/2}\}$ acting on $\mathbb{R}^3$ by a $\pi$ rotation about the $z$ axis,*

$$C^{1/2}(x, y, z) = (-x, -y, z). \tag{6.5}$$

**Example 6.2.** *Desymmetrization of Lorenz flow:* *(continuation of example 6.1) Lorenz equation (6.4) is equivariant under (6.5), the action of order-2 group $C_2 = \{e, C^{1/2}\}$, where $C^{1/2}$ is $[x, y]$-plane, half-cycle rotation by $\pi$ about the $z$-axis:*

$$(x, y, z) \to C^{1/2}(x, y, z) = (-x, -y, z). \tag{6.6}$$

*$(C^{1/2})^2 = 1$ condition decomposes the state space into two linearly irreducible subspaces $\mathcal{M} = \mathcal{M}^+ \oplus \mathcal{M}^-$, the $z$-axis $\mathcal{M}^+$ and the $[x, y]$ plane $\mathcal{M}^-$, with projection operators onto the two subspaces given by*

$$\mathbf{P}^+ = \frac{1}{2}(1 + C^{1/2}) = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \quad \mathbf{P}^- = \frac{1}{2}(1 - C^{1/2}) = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{pmatrix}. \tag{6.7}$$

Table 6.1: $D_3$ correspondence between the binary labeled fundamental domain prime cycles $\tilde{p}$ and the full 3-disk ternary labeled cycles $p$, together with the $D_3$ transformation that maps the end point of the $\tilde{p}$ cycle into the irreducible segment of the $p$ cycle. White spaces in the above ternary sequences mark repeats of the irreducible segment; for example, the full space 12-cycle 1212 3131 2323 consists of 1212 and its symmetry related segments 3131, 2323. The multiplicity of $p$ cycle is $m_p = 6n_{\tilde{p}}/n_p$. The shortest pair of fundamental domain cycles related by time reversal (but no spatial symmetry) are the 6-cycles $\overline{001011}$ and $\overline{001101}$.

| $\tilde{p}$ | $p$ | $\mathbf{g}_{\tilde{p}}$ | $\tilde{p}$ | $p$ | $\mathbf{g}_{\tilde{p}}$ |
|---|---|---|---|---|---|
| 0 | 1 2 | $\sigma_{12}$ | 000001 | 121212 131313 | $\sigma_{23}$ |

| 01011 | 12131 23212 31323 | $C$ | 0000111 | 1212123 | $e$ |
| 01111 | 12132 13123 | $\sigma_{23}$ | $\cdots$ | $\cdots$ | $\cdots$ |

*so*

$$\left( \begin{array}{c} \dot{x}_- \\ \dot{y}_- \end{array} \right) = \left( \begin{array}{cc} -\sigma & \sigma \\ \rho & -1 \end{array} \right) \left( \begin{array}{c} x_- \\ y_- \end{array} \right) + \left( \begin{array}{c} 0 \\ -z\,x_- \end{array} \right)$$

$$\dot{z}_+ = -b\,z_+ + \frac{1}{4}(x_+ + x_-)(y_+ + y_-)\,, \tag{6.8}$$

*where $z_+ = z$. As $(\dot{x}_+, \dot{y}_+) = (0,0)$, values of $(x_+, y_+)$ are conserved parts of the initial condition. We define the fundamental domain by the (arbitrary) condition $\hat{x}_- \geq 0$, and whenever exits the domain, we replace the function dependence by the corresponding fundamental domain coordinates,*

$$(x_-, y_-) = C^{1/2}(\hat{x}_-, \hat{y}_-) = (-\hat{x}_-, -\hat{y}_-) \quad \text{if} \quad x_- < 0\,,$$

*and record that we have applied $C^{1/2}$ (that is the 'reconstruction equation' in the case of a discrete symmetry). When we integrate (6.8), the trajectory coordinates $(\hat{x}_-(t), \hat{y}_-(t))$ are discontinuous whenever the trajectory crosses the fundamental domain border. That, however, we do not care about - the only thing we need are the Poincaré section points and the Poincaré return map in the fundamental domain.*

*Poincaré section hypersurface can be specified implicitly by a single condition, through a function $U(x)$ that is zero whenever a point $x$ is on the Poincaré section,*

$$\hat{x} \in \mathcal{P} \quad \text{iff} \quad U(\hat{x}) = 0\,. \tag{6.9}$$

*In order that there is only one copy of the section in the fundamental domain, this condition has to be invariant, $U(g\hat{x}) = U(\hat{x})$ for $g \in G$, or, equivalently, the normal to it has to be equivariant*

$$\partial_j U(g\hat{x}) = g\partial_j U(\hat{x}) \quad \text{for} \quad g \in G\,. \tag{6.10}$$
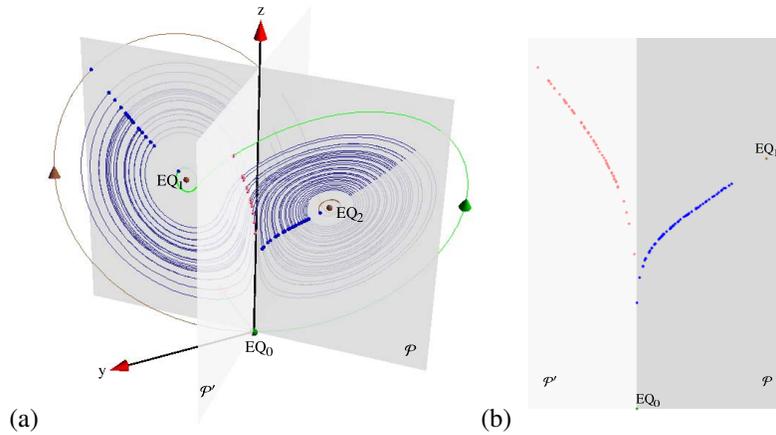

(a) (b)

Figure 6.2:  (a) Lorenz flow cut by $y = x$ Poincaré section plane $\mathcal{P}$ through the $z$ axis and both $\mathrm{E}_{1,2}$ equilibria.  Points where flow pierces into section are marked by dots. To aid visualization of the flow near the $\mathrm{E}_0$ equilibrium, the flow is cut by the second Poincaré section, $\mathcal{P}'$, through $y = -x$ and the $z$ axis. (b) Poincaré sections $\mathcal{P}$ and $\mathcal{P}'$ laid side-by-side.                                                                                    (E. Siminos)

*There are two kinds of compact (finite-time) orbits.  Periodic orbits $x(T_p) = x(T_p)$ are either self dual under rotation $C^{1/2}$, or appear in pairs related by $C^{1/2}$; in the fundamental domain there is only one copy $\hat{x}(T_p) = \hat{x}(T_p)$ of each.  Relative periodic orbits (or 'pre-periodic orbits') $\hat{x}(T_p) = C^{1/2}x(T_p)$ they are periodic orbits.*

*As the flow is $C_2$-invariant, so is its linearization $\dot{x} = Ax$.  Evaluated at $\mathrm{E}_0$, $A$ commutes with $C^{1/2}$, and the $\mathrm{E}_0$ stability matrix $A$ decomposes into $[x, y]$ and $z$ blocks.*

*The 1-dimensional $\mathcal{M}^+$ subspace is the fixed-point subspace, with the $z$-axis points left point-wise invariant under the group action*

$$\mathcal{M}^+ = \mathrm{Fix}\,(C_2) = \{x \in \mathcal{M} \mid g\,x = x \text{ for } g \in \{e, C^{1/2}\}\} \tag{6.11}$$

*(here $x = (x, y, z)$ is a 3-dimensional vector, not the coordinate $x$). A $C_2$-fixed point $x(t)$ in $\mathrm{Fix}\,(C_2)$ moves with time, but according to (6.2) remains within $x(t) \in \mathrm{Fix}\,(C_2)$ for all times; the subspace $\mathcal{M}^+ = \mathrm{Fix}\,(C_2)$ is flow invariant. In case at hand this jargon is a bit of an overkill: clearly for $(x, y, z) = (0, 0, z)$ the full state space Lorenz equation (6.4) is reduced to the exponential contraction to the $\mathrm{E}_0$ equilibrium,*

$$\dot{z} = -b\,z\,. \tag{6.12}$$

*However, for higher-dimensional flows the flow-invariant subspaces can be high-dimensional, with interesting dynamics of their own. Even in this simple case this subspace plays an important role as a topological obstruction: the orbits can neither enter it nor exit it, so the number of windings of a trajectory around it provides a natural, topological symbolic dynamics.*

*The $\mathcal{M}^-$ subspace is, however, not flow-invariant, as the nonlinear terms $\dot{z} = xy - bz$ in the Lorenz equation (6.4) send all initial conditions within $\mathcal{M}^- = (x(0), y(0), 0)$ into the full, $z(t) \neq 0$ state space $\mathcal{M}/\mathcal{M}^+$.*

*By taking as a Poincaré section any $C^{1/2}$-equivariant, non-self-intersecting surface that contains the $z$ axis, the state space is divided into a half-space fundamental domain*
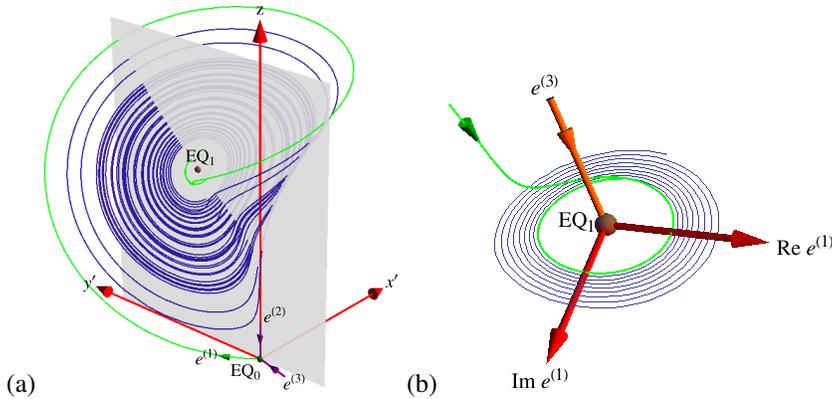

Figure 6.3: (a) Lorenz attractor plotted in $[\hat{x}, \hat{y}, z]$, the doubled-polar angle coordinates (6.13), with points related by $\pi$-rotation in the $[x, y]$ plane identified. Stable eigenvectors of $E_0$: $\mathbf{e}^{(3)}$ and $\mathbf{e}^{(2)}$, along the $z$ axis (6.12). Unstable manifold orbit $W^u(E_0)$ (green) is a continuation of the unstable $\mathbf{e}^{(1)}$ of $E_0$. (b) Blow-up of the region near $E_1$: The unstable eigenplane of $E_1$ defined by $\mathrm{Re}\,\mathbf{e}^{(2)}$ and $\mathrm{Im}\,\mathbf{e}^{(2)}$, the stable eigenvector $\mathbf{e}^{(3)}$. The descent of the $E_0$ unstable manifold (green) defines the innermost edge of the strange attractor. As it is clear from (a), it also defines its outermost edge. (E. Siminos)

$\tilde{\mathcal{M}} = \mathcal{M}/C_2$ *and its* $180^o$ *rotation* $C^{1/2}\tilde{\mathcal{M}}$. *An example is afforded by the* $\mathcal{P}$ *plane section of the Lorenz flow in figure* 6.1. *Take the fundamental domain* $\tilde{\mathcal{M}}$ *to be the half-space between the viewer and* $\mathcal{P}$. *Then the full Lorenz flow is captured by re-injecting back into* $\tilde{\mathcal{M}}$ *any trajectory that exits it, by a rotation of* $\pi$ *around the* $z$ *axis.*

*As any such* $C^{1/2}$*-invariant section does the job, a choice of a 'fundamental domain' is here largely mater of taste. For purposes of visualization it is convenient to make the double-cover nature of the full state space by* $\tilde{\mathcal{M}}$ *explicit, through any state space redefinition that maps a pair of points related by symmetry into a single point. In case at hand, this can be easily accomplished by expressing* $(x, y)$ *in polar coordinates* $(x, y) = (r\cos\theta, r\sin\theta)$*, and then plotting the flow in the* 'doubled-polar angle representation:'

$$(\hat{x}, \hat{y}, z) = (r\cos 2\theta, r\sin 2\theta, z) = ((x^2 - y^2)/r, 2xy/r, z), \qquad (6.13)$$

*as in figure* 6.1 *(a). In contrast to the original* $G$*-equivariant coordinates* $[x, y, z]$*, the Lorenz flow expressed in the new coordinates* $[\hat{x}, \hat{y}, z]$ *is* $G$*-invariant. In this representation the* $\tilde{\mathcal{M}} = \mathcal{M}/C_2$ *fundamental domain flow is a smooth, continuous flow, with (any choice of) the fundamental domain stretched out to seamlessly cover the entire* $[\hat{x}, \hat{y}]$ *plane.*

*(E. Siminos and J. Halcrow)*

# Exercises

6.1. **3-disk symbolic dynamics.**    As periodic trajectories will turn out to be our main tool to breach deep into the realm of chaos, it pays to start familiarizing oneself with them now by sketching and counting the few shortest prime cycles. Show that the 3-disk pinball has $3 \cdot 2^{n-1}$ itineraries of length $n$. List periodic orbits of lengths 2, 3, 4, 5, $\cdots$. Verify that the shortest 3-disk prime cycles are 12, 13, 23, 123, 132, 1213, 1232, 1323, 12123, $\cdots$. Try to sketch them.   (continued in exercise 6.3)

A comment about exercise 6.1, exercise 6.2, and exercise 6.3: If parts of these problems seem trivial - they are.  The intention is just to check that you understand what these symbolic dynamics codings are - the main message is that the really smart coding (fundamental domain) is 1-to-1 given by the group theory operations that map a point in the fundamental domain to where it is in the full state space. This observation you might not find deep, but it is - instead of *absolute* labels, in presence of symmetries one only needs to keep track of *relative* motions, from domain to domain, does not matter which domain in absolute coordinates - that is what group actions do. And thus the word '*relative*' creeps into this exposition.

6.2. **Reduction of 3-disk symbolic dynamics to binary.**    (continued from exercise 6.1)

   (a) Verify that the 3-disk cycles
   $\{\overline{1\,2}, \overline{1\,3}, \overline{2\,3}\}$, $\{\overline{1\,2\,3}, \overline{1\,3\,2}\}$, $\{\overline{12\,13} + 2 \text{ perms.}\}$,
   $\{\overline{121\,232\,313} + 5 \text{ perms.}\}$, $\{\overline{121\,323} + 2 \text{ perms.}\}$, $\cdots$,
   correspond to the fundamental domain cycles $\overline{0}$, $\overline{1}$, $\overline{01}$, $\overline{001}$, $\overline{011}$, $\cdots$ respectively.

   (b) Check the reduction for short cycles in table 6.1 by drawing them both in the full 3-disk system and in the fundamental domain, as in figure 6.1.

   (c) Optional: Can you see how the group elements listed in table 6.1 relate irreducible segments to the fundamental domain periodic orbits?

   (continued in exercise 6.3)

6.3. **3-disk fundamental domain cycles.**    Try to sketch $\overline{0}$, $\overline{1}$, $\overline{01}$, $\overline{001}$, $\overline{011}$, $\cdots$.  in the fundamental domain, and interpret the symbols $\{0, 1\}$ by relating them to topologically distinct types of collisions. Compare with table 6.1. Then try to sketch the location of periodic points in the Poincaré section of the billiard flow. The point of this exercise is that while in the configuration space longer cycles look like a hopeless jumble, in the Poincaré section they are clearly and logically ordered. The Poincaré section is always to be preferred to projections of a flow onto the configuration space coordinates, or any other subset of state space coordinates which does not respect the topological organization of the flow.

6.4. **C$_2$-equivariance of Lorenz system.** Verify that the vector field in Lorenz equations (6.4)

$$\dot{x} = v(x) = \begin{bmatrix} \dot{x} \\ \dot{y} \\ \dot{z} \end{bmatrix} = \begin{bmatrix} \sigma(y-x) \\ \rho x - y - xz \\ xy - bz \end{bmatrix} \qquad (6.14)$$

is equivariant under the action of cyclic group C$_2$ = $\{e, C^{1/2}\}$ acting on $\mathbb{R}^3$ by a $\pi$ rotation about the $z$ axis,

$$C^{1/2}(x, y, z) = (-x, -y, z),$$

as claimed in example 6.1.

6.5. **Proto-Lorenz system.** Here we quotient out the C$_2$ symmetry by constructing an explicit "intensity" representation of the desymmetrized Lorenz flow.

1. Rewrite the Lorenz equation (6.4) in terms of variables

$$(u, v, z) = (x^2 - y^2, 2xy, z), \qquad (6.15)$$

show that it takes form

$$\begin{bmatrix} \dot{u} \\ \dot{v} \\ \dot{z} \end{bmatrix} = \begin{bmatrix} -(\sigma+1)u + (\sigma-r)v + (1-\sigma)N + vz \\ (r-\sigma)u - (\sigma+1)v + (r+\sigma)N - uz - Nz \\ v/2 - bz \end{bmatrix}$$

$$N = \sqrt{u^2 + v^2}. \qquad (6.16)$$

2. Show that this is the (Lorenz)/C$_2$ quotient map for the Lorenz flow, i.e., that it identifies points related by the $\pi$ rotation (6.6).

3. Show that (6.15) is invertible. Where does the inverse not exist?

4. Compute the equilibria of proto-Lorenz and their stabilities. Compare with the equilibria of the Lorenz flow.

5. Plot the strange attractor both in the original form (6.4) and in the proto-Lorenz form (6.16)
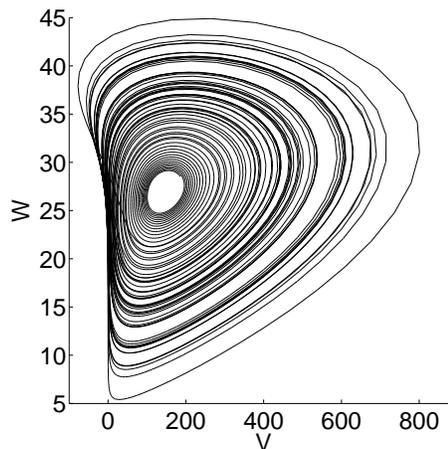

for the Lorenz parameter values $\sigma = 10$, $b = 8/3$, $\rho = 28$. Topologically, does it resemble more the Lorenz, or the Rössler attractor, or neither? (plot by J. Halcrow)

7. Show that a periodic orbit of the proto-Lorenz is either a periodic orbit or a relative periodic orbit of the Lorenz flow.

8. Show that if a periodic orbit of the proto-Lorenz is also periodic orbit of the Lorenz flow, their Floquet multipliers are the same. How do the Floquet multipliers of relative periodic orbits of the Lorenz flow relate to the Floquet multipliers of the proto-Lorenz?

9 Show that the coordinate change (6.15) is the same as rewriting

$$
\begin{aligned}
\dot{r} &= \frac{r}{2} \left( -\sigma - 1 + (\sigma + \rho - z) \sin 2\theta \right. \\
&\quad \left. + (1 - \sigma) \cos 2\theta \right) \\
\dot{\theta} &= \frac{1}{2} \left( -\sigma + \rho - z + (\sigma - 1) \sin 2\theta \right. \\
&\quad \left. + (\sigma + \rho - z) \cos 2\theta \right) \\
\dot{z} &= -bz + \frac{r^2}{2} \sin 2\theta \, .
\end{aligned} \tag{6.17}
$$

in variables

$$
(u, v) = (r^2 \cos 2\theta, r^2 \sin 2\theta) \, ,
$$

i.e., squaring a complex number $z = x + iy$, $z^2 = u + iv$.
